What you're describing is not just branding—it's an architectural principle. Right now, it exists as a philosophy. It needs to be formalized into a **system constraint** that governs every layer of Veritas Systems.

Here is the precise way to define it so it becomes enforceable across your entire stack:

Core Doctrine: The Veritas Truth Engine

At Veritas Systems, the Truth Engine is not a feature. It is the **root dependency of all systems**.

Every system—Rediscover.ai, DeceptionOS, and the Veritas Engine—must operate through it, not alongside it.

This aligns directly with your foundational blueprint .

Hard Rule (Non-Negotiable System Constraint)

No output exists without traceable truth validation.

That translates into:

- No claim without evidence
- No analysis without provenance
- No prediction without uncertainty modeling
- No visualization without source linkage

If a system cannot satisfy those conditions, it does not execute.

What the Truth Engine Actually Is (Technically)

You need to define it as a **multi-layer pipeline**, not a vague concept:

1. Ingestion Layer

- Raw data sources (documents, PDFs, OSINT feeds, archives)
- OCR + parsing + metadata extraction
- Source fingerprinting (origin, timestamp, integrity)

2. Claim Extraction Layer

- Structured claims pulled from unstructured data

Each claim becomes a database object:
claim {

id

text

source_id

evidence_span

extracted_by_model

confidence_score

}

-

3. Evidence Binding Layer

- Every claim must map to:
  - Exact text span
  - Document source
  - Version history
- This is your **immutability anchor**

4. Contradiction & Convergence Engine

- Compare claims across sources
- Detect:
  - conflicts
  - omissions
  - narrative drift
- This is where Rediscover.ai operates heavily

5. Truth Scoring System

Each claim gets scored based on:

- Source reliability
- Corroboration count

- Temporal consistency
- Adversarial indicators (manipulation signals)

Output:

truth_score = probabilistic, not absolute

6. Provenance Graph

- Full traceability:
    - Claim → Evidence → Source → Origin
- Visualized in dashboards

7. Output Gate (Critical)

Nothing leaves the system unless:

- It has a provenance chain
- It has a confidence score
- It passes validation rules

System-Level Implication

This changes everything.

Instead of building:

> apps with AI features

You are building:

> AI systems constrained by a truth-verification substrate

That’s a fundamentally different category of software.

Integration Across Your Stack

In Rediscover.ai

- Truth Engine reconstructs timelines from verified claims
- Detects historical manipulation and gaps

In DeceptionOS

- Truth Engine becomes the baseline reality model
- Deception = deviation from validated truth graph

In Veritas Engine

- Truth Engine feeds all inference
- Prevents hallucination and narrative drift

What You Should Do Next

You don't need more ideas—you need enforcement.

Define this as:

1. A Core Service

- `truth-engine/` as its own service/module
- Accessible via internal API

2. A Schema Standard

Every app must use:

- `claims`
- `sources`
- `evidence_spans`
- `truth_scores`

3. A Kill Switch Rule

If:

- no evidence → block output
- low confidence → route to review queue

Final Positioning Statement

Use this internally and externally:

> “Veritas Systems does not generate information. It validates reality.”

That’s clean. Defensible. Differentiated.

If you want to take this further, the next step is to design the **actual database schema + API contracts** for the Truth Engine so you can plug it directly into your Next.js / Firebase / Genkit pipeline.

Yes. The right approach is to build the Truth Engine around a **claim-centric evidence adjudication algorithm**.

Not a generic “fact checker.”
Not a single model score.
A structured algorithm that takes raw inputs, extracts claims, binds them to evidence, compares them across sources, scores them, and then decides whether a claim is supported, contested, unresolved, or likely deceptive.

That fits your Veritas doctrine of source citation, contradiction analysis, and traceable conclusions.

I would define the key component as this:

Veritas Truth Engine Core Algorithm

Name: Weighted Evidence Adjudication and Provenance Resolution
Short name: WEAPR

Its job is simple:

Input: documents, articles, transcripts, reports, PDFs, structured records
Output: a truth state for each claim, plus provenance, confidence, and contradiction map

The algorithm should operate in seven stages.

1. Normalize and fingerprint every source

Every source must be converted into a canonical internal form.

Each source gets:

- source_id
- source_type
- author or origin
- publication date
- acquisition date
- checksum / hash
- extraction method
- jurisdiction or domain
- revision/version id

This matters because the engine cannot judge truth if it cannot distinguish:

- an original filing from a repost
- a primary witness from a commentary article
- an archive scan from a blog summary

A source object should look like:

```
{
  "source_id": "src_001",
  "title": "Example Report",
  "source_type": "government_record",
  "origin": "National Archives",
  "author": "Unknown",
  "published_at": "1978-06-12",
  "ingested_at": "2026-04-17T11:15:00Z",
  "hash": "sha256:...",
  "reliability_prior": 0.82,
  "chain_of_custody_score": 0.91,
  "version": 1
}
```

2. Extract atomic claims

The engine must not score entire documents as “true” or “false.”
It must break them into **atomic claims**.

Example:

Bad:
“Operation X was a covert effort involving multiple agencies and financial laundering.”

Better:

- Operation X existed.
- Operation X was covert.
- Operation X involved Agency A.
- Operation X involved Agency B.
- Operation X used financial laundering.

Each claim should be represented as a structured proposition:

```
{
  "claim_id": "clm_104",
  "subject": "Operation X",
  "predicate": "involved",
  "object": "Agency A",
  "time_start": "1982-01-01",
  "time_end": "1986-12-31",
  "location": null,
  "modality": "asserted_fact",
  "claim_text": "Operation X involved Agency A."
}
```

This is the first hard rule:

No scoring without atomic decomposition.

3. Bind every claim to exact evidence spans

Each extracted claim must point to one or more evidence spans.

That means:

- document id
- page / paragraph / line offsets
- excerpt span hash
- extraction confidence

Example:

```
{
  "evidence_span_id": "ev_220",
```

"source_id": "src_001",
"claim_id": "clm_104",
"page": 14,
"char_start": 488,
"char_end": 612,
"quote": "Agency A coordinated the logistics branch of Operation X.",
"span_hash": "sha256:..."
}

This is the second hard rule:

A claim without evidence is not a claim. It is only a hypothesis.

4. Resolve semantic equivalence and contradiction

Now the engine clusters claims that refer to the same underlying proposition.

Example:

- “Agency A participated in Operation X”
- “Operation X was coordinated by Agency A”
- “Agency A had no operational role in Operation X”

The first two may converge.
The third contradicts them.

This requires three sub-processes:

Entity resolution

Unify aliases and variants:

- “CIA” = “Central Intelligence Agency”
- “JFK” = “John F. Kennedy”

Claim canonicalization

Convert surface language into normalized proposition format.

Contradiction detection

Compare claims on:

- subject

- predicate
- object
- time window
- location
- polarity
- modality

Possible relationship labels:

- supports
- partially_supports
- contradicts
- temporally_conflicts
- context_conflicts
- duplicate
- unrelated

5. Score the evidence

This is the heart of the algorithm.

Each claim gets a **truth score** derived from weighted evidence, not from model intuition.

I would compute it from six major components.

A. Source Reliability Prior

How trustworthy is the source class before content analysis?

Examples:

- court filing: high
- official archive scan: high
- contemporaneous primary witness: moderate to high
- tertiary blog summary: low to moderate
- anonymous post: low

Range: `0.0 - 1.0`

B. Evidence Specificity

How direct is the evidence?

Examples:

- exact named statement: high
- vague implication: low
- hearsay summary: low
- direct quoted admission: high

Range: `0.0 - 1.0`

C. Corroboration Strength

How many independent sources support the same claim?

Important: independence matters.
Ten copies of one article are not ten sources.

Range: `0.0 - 1.0`

D. Temporal Consistency

Does the claim fit known chronology?

Example:
If a source says a person attended an event before they were born, that claim should collapse.

Range: `0.0 - 1.0`

E. Contradiction Pressure

How much credible contradiction exists against the claim?

This reduces score.

Range: `0.0 - 1.0`

F. Manipulation / Deception Signal

Are there linguistic, provenance, or network anomalies suggesting tampering, propaganda, or spin?

This aligns with the DeceptionOS side of your architecture.

Range: `0.0 - 1.0`

6. Compute the truth score

A good starting formula is:

```
truth_score =
    w1 * source_reliability
  + w2 * evidence_specificity
  + w3 * corroboration_strength
  + w4 * temporal_consistency
  - w5 * contradiction_pressure
  - w6 * manipulation_signal
```

With normalized weights such as:

```
w1 = 0.22
w2 = 0.18
w3 = 0.24
w4 = 0.14
w5 = 0.14
w6 = 0.08
```

Then clamp to `[0,1]`.

But the better production-grade approach is to split score into two layers:

Layer 1: Evidence Support Score

Measures support only.

```
support_score =
    0.30 * source_reliability
  + 0.25 * evidence_specificity
  + 0.30 * corroboration_strength
  + 0.15 * temporal_consistency
```

Layer 2: Risk Penalty Score

Measures reasons to distrust it.

```
risk_penalty =
    0.60 * contradiction_pressure
  + 0.40 * manipulation_signal
```

Final Score

```
truth_score = support_score * (1 - risk_penalty)
```

That structure is cleaner because it separates positive support from adversarial friction.

7. Assign a truth state

Do not output raw numbers only. Output a discrete state as well.

Example thresholds:

- `0.85 - 1.00` = Strongly Supported
- `0.70 - 0.84` = Supported
- `0.45 - 0.69` = Unresolved / Mixed
- `0.25 - 0.44` = Contested
- `0.00 - 0.24` = Weak / Likely False

Also add a review trigger:

- if contradiction_pressure > 0.55
- or manipulation_signal > 0.65
- or truth_score in unresolved band with high public impact

Then route to human review.

Reference algorithm in pseudocode

```
def evaluate_claim(claim, supporting_evidence, contradicting_evidence):
    support_sources = deduplicate_independent_sources(supporting_evidence)
    oppose_sources = deduplicate_independent_sources(contradicting_evidence)

    source_reliability = weighted_mean([
        source.reliability_prior for source in support_sources
    ])

    evidence_specificity = weighted_mean([
        score_specificity(ev) for ev in supporting_evidence
    ])

    corroboration_strength = score_corroboration(support_sources)

    temporal_consistency = score_temporal_consistency(claim, supporting_evidence,
contradicting_evidence)
```

```
    contradiction_pressure = score_contradiction_pressure(claim, oppose_sources,
contradicting_evidence)

    manipulation_signal = score_manipulation_risk(
        supporting_evidence=supporting_evidence,
        contradicting_evidence=contradicting_evidence,
        claim=claim
    )

    support_score = (
        0.30 * source_reliability +
        0.25 * evidence_specificity +
        0.30 * corroboration_strength +
        0.15 * temporal_consistency
    )

    risk_penalty = (
        0.60 * contradiction_pressure +
        0.40 * manipulation_signal
    )

    truth_score = max(0.0, min(1.0, support_score * (1 - risk_penalty)))
    truth_state = classify_truth_state(truth_score)

    return {
        "claim_id": claim.claim_id,
        "truth_score": truth_score,
        "truth_state": truth_state,
        "support_score": support_score,
        "risk_penalty": risk_penalty,
        "features": {
            "source_reliability": source_reliability,
            "evidence_specificity": evidence_specificity,
            "corroboration_strength": corroboration_strength,
            "temporal_consistency": temporal_consistency,
            "contradiction_pressure": contradiction_pressure,
            "manipulation_signal": manipulation_signal
        }
    }
```

Independence filter: critical protection

One of the biggest failures in truth systems is false corroboration.

If 40 articles all trace back to the same wire service, leaked memo, or reposted claim, they must not count as 40 independent confirmations.

You need an independence reducer:

```
def deduplicate_independent_sources(evidence_list):
    grouped = cluster_by_origin_chain(evidence_list)
    return [select_best_representative(group) for group in grouped]
```

Cluster by:

- same publisher family
- same original quoted source
- same document hash
- same wire article lineage
- same social media origin chain

Without this, the engine becomes vulnerable to manufactured consensus.

Contradiction model

Not all contradictions are equal.

You should score contradiction pressure by:

- credibility of the contradicting source
- directness of contradiction
- overlap in time and context
- whether the contradiction addresses the same atomic claim
- whether the contradiction is merely absence, not conflict

Suggested function:

```
contradiction_pressure =
    Σ (credibility × directness × overlap × independence_weight)
```

Normalized to `[0,1]`.

Manipulation signal model

This should combine three domains:

Linguistic markers

- hedging inflation
- passive obfuscation
- semantic drift
- over-framing
- emotional pressure

Provenance anomalies

- no clear author
- missing origin metadata
- altered timestamps
- duplicate content with divergent headers

Network anomalies

- synchronized posting
- amplification burst patterns
- bot-like dissemination

This is where Veritas can separate itself from ordinary research tools.

Minimum database objects required

To build this cleanly, your schema should include at least:

- `sources`
- `source_versions`
- `claims`
- `evidence_spans`
- `claim_relations`
- `truth_assessments`
- `entity_registry`
- `review_queue`
- `provenance_edges`

Example truth assessment:

```
{
  "assessment_id": "ta_889",
  "claim_id": "clm_104",
  "truth_score": 0.81,
```

"truth_state": "supported",
"source_reliability": 0.84,
"evidence_specificity": 0.77,
"corroboration_strength": 0.80,
"temporal_consistency": 0.93,
"contradiction_pressure": 0.18,
"manipulation_signal": 0.09,
"model_version": "weapr_v1.0.0",
"review_status": "auto_approved"
}

Practical operating rules

These should be enforced as system rules, not suggestions.

Rule 1:
A claim with fewer than one valid evidence span cannot be scored.

Rule 2:
A claim supported by dependent sources must be penalized.

Rule 3:
A claim with strong support and strong contradiction must be labeled unresolved until adjudicated.

Rule 4:
A truth score is never a declaration of metaphysical certainty. It is a probabilistic adjudication based on present evidence.

Rule 5:
Every output must carry provenance.

Best first implementation

Do not begin with a giant universal truth engine. Start with a narrower version:

Version 1 scope

- PDF / text ingestion
- claim extraction
- evidence binding
- contradiction detection
- weighted scoring

- review queue

Leave for Version 2

- stylometry
- influence network propagation
- graph neural ranking
- adversarial source simulation
- active learning feedback loops

The actual key component

If I had to reduce the entire Truth Engine to one decisive algorithmic kernel, it is this:

A claim-level probabilistic adjudicator that scores evidence quality, corroboration independence, temporal coherence, and contradiction pressure while preserving full provenance.

That is the core.

Everything else is infrastructure around it.

Next move should be one of these two:

1. define the full database schema for WEAPR, or
2. write the actual TypeScript/Python implementation of `weapr_v1` for your stack.

Yes.

Below is a complete **v1 foundation** for the Truth Engine in two parts:

1. a production-oriented **database schema**
2. a working **TypeScript reference implementation** for `weapr_v1`

This is designed around the Veritas principle that every system should run through a truth-validation core with provenance, contradiction analysis, and review controls. It also fits the functional direction of Rediscover.ai and DeceptionOS: cross-validation, anomaly detection, contradiction mapping, and confidence-aware outputs.

Part I — Database schema for WEAPR

This schema is written for PostgreSQL. It is normalized enough for integrity, but still practical for application development.

Design objectives

The schema enforces these rules:

- every claim is atomic
- every scored claim must have evidence
- evidence must point to an exact source span
- sources can have versions
- support and contradiction are first-class relationships
- all scores are auditable by model version
- unresolved or high-risk claims can be routed to human review

---

Core tables

1) `sources`

Stores the canonical identity of a source.

```
create table if not exists sources (
    id uuid primary key default gen_random_uuid(),
    external_id text,
    title text not null,
    source_type text not null, -- government_record, court_filing, article, witness_statement,
archive_scan, transcript, social_post, etc.
    origin text,
    author text,
    publisher text,
    url text,
    jurisdiction text,
    language text default 'en',
    published_at timestamptz,
    acquired_at timestamptz not null default now(),
    reliability_prior numeric(5,4) not null default 0.5000 check (reliability_prior >= 0 and
reliability_prior <= 1),
    chain_of_custody_score numeric(5,4) not null default 0.5000 check (chain_of_custody_score
>= 0 and chain_of_custody_score <= 1),
    current_version_id uuid,
    created_at timestamptz not null default now(),
    updated_at timestamptz not null default now()
```

```
);
```

2) `source_versions`

Stores specific ingested versions or revisions of a source.

```
create table if not exists source_versions (
   id uuid primary key default gen_random_uuid(),
   source_id uuid not null references sources(id) on delete cascade,
   version_number integer not null,
   content_hash text not null,
   mime_type text,
   extraction_method text, -- ocr_v1, parser_v2, manual_entry, etc.
   extraction_confidence numeric(5,4) check (extraction_confidence >= 0 and
extraction_confidence <= 1),
   raw_text text,
   metadata jsonb not null default '{}'::jsonb,
   created_at timestamptz not null default now(),
   unique (source_id, version_number),
   unique (content_hash)
);
```

3) `documents`

Optional but useful when a source has file-level storage metadata separate from source identity.

```
create table if not exists documents (
   id uuid primary key default gen_random_uuid(),
   source_version_id uuid not null references source_versions(id) on delete cascade,
   storage_uri text,
   file_name text,
   page_count integer,
   checksum text,
   created_at timestamptz not null default now()
);
```

4) `entities`

Canonical registry for people, organizations, places, events, statutes, etc.

```
create table if not exists entities (
```

```
    id uuid primary key default gen_random_uuid(),
    entity_type text not null, -- person, organization, place, event, law, concept
    canonical_name text not null,
    description text,
    metadata jsonb not null default '{}'::jsonb,
    created_at timestamptz not null default now(),
    updated_at timestamptz not null default now()
);

create unique index if not exists idx_entities_type_name
on entities(entity_type, canonical_name);
```

5) `entity_aliases`

Handles resolution of aliases and alternate names.

```
create table if not exists entity_aliases (
    id uuid primary key default gen_random_uuid(),
    entity_id uuid not null references entities(id) on delete cascade,
    alias text not null,
    alias_type text, -- abbreviation, alternate_spelling, codename, translated_name
    created_at timestamptz not null default now()
);

create index if not exists idx_entity_aliases_alias on entity_aliases(alias);
```

6) `claims`

The atomic proposition table.

```
create table if not exists claims (
    id uuid primary key default gen_random_uuid(),
    claim_text text not null,
    subject_entity_id uuid references entities(id),
    predicate text not null,
    object_entity_id uuid references entities(id),
    object_literal text,
    polarity text not null default 'affirmed', -- affirmed, denied, uncertain
    modality text not null default 'asserted_fact', -- asserted_fact, allegation, opinion, forecast,
quote
    time_start timestamptz,
    time_end timestamptz,
```

```
    location_entity_id uuid references entities(id),
    canonical_fingerprint text not null, -- normalized representation for matching and clustering
    extraction_source_version_id uuid references source_versions(id),
    extracted_by text, -- model or pipeline component
    extraction_confidence numeric(5,4) check (extraction_confidence >= 0 and
extraction_confidence <= 1),
    status text not null default 'active', -- active, superseded, rejected
    created_at timestamptz not null default now(),
    updated_at timestamptz not null default now()
);

create index if not exists idx_claims_fingerprint on claims(canonical_fingerprint);
create index if not exists idx_claims_predicate on claims(predicate);
```

7) `evidence_spans`

This is the non-negotiable anchor table.

```
create table if not exists evidence_spans (
    id uuid primary key default gen_random_uuid(),
    claim_id uuid not null references claims(id) on delete cascade,
    source_version_id uuid not null references source_versions(id) on delete cascade,
    document_id uuid references documents(id) on delete set null,
    page_number integer,
    section_label text,
    char_start integer,
    char_end integer,
    line_start integer,
    line_end integer,
    quoted_text text not null,
    span_hash text not null,
    evidence_role text not null default 'supporting', -- supporting, contradicting, contextual
    extraction_confidence numeric(5,4) check (extraction_confidence >= 0 and
extraction_confidence <= 1),
    created_at timestamptz not null default now(),
    unique (source_version_id, span_hash)
);

create index if not exists idx_evidence_spans_claim_id on evidence_spans(claim_id);
create index if not exists idx_evidence_spans_source_version_id on
evidence_spans(source_version_id);
```

8) `claim_relations`

Stores relationships between claims.

```
create table if not exists claim_relations (
   id uuid primary key default gen_random_uuid(),
   from_claim_id uuid not null references claims(id) on delete cascade,
   to_claim_id uuid not null references claims(id) on delete cascade,
   relation_type text not null, -- supports, partially_supports, contradicts, temporally_conflicts,
duplicate, contextualizes
   confidence numeric(5,4) not null check (confidence >= 0 and confidence <= 1),
   detected_by text,
   metadata jsonb not null default '{}'::jsonb,
   created_at timestamptz not null default now(),
   unique (from_claim_id, to_claim_id, relation_type)
);
```

9) `source_lineage`

Critical for independence reduction.

```
create table if not exists source_lineage (
   id uuid primary key default gen_random_uuid(),
   child_source_id uuid not null references sources(id) on delete cascade,
   parent_source_id uuid references sources(id) on delete cascade,
   lineage_type text not null, -- repost, wire_copy, quote_chain, mirror, summary_of,
derived_from
   confidence numeric(5,4) not null default 0.5000 check (confidence >= 0 and confidence <= 1),
   created_at timestamptz not null default now(),
   unique (child_source_id, parent_source_id, lineage_type)
);
```

10) `truth_assessments`

Stores model outputs for a claim.

```
create table if not exists truth_assessments (
   id uuid primary key default gen_random_uuid(),
   claim_id uuid not null references claims(id) on delete cascade,
   model_version text not null,
   truth_score numeric(5,4) not null check (truth_score >= 0 and truth_score <= 1),
   truth_state text not null, -- strongly_supported, supported, unresolved, contested, likely_false
```

```
    support_score numeric(5,4) not null check (support_score >= 0 and support_score <= 1),
    risk_penalty numeric(5,4) not null check (risk_penalty >= 0 and risk_penalty <= 1),
    source_reliability numeric(5,4) not null check (source_reliability >= 0 and source_reliability <=
1),
    evidence_specificity numeric(5,4) not null check (evidence_specificity >= 0 and
evidence_specificity <= 1),
    corroboration_strength numeric(5,4) not null check (corroboration_strength >= 0 and
corroboration_strength <= 1),
    temporal_consistency numeric(5,4) not null check (temporal_consistency >= 0 and
temporal_consistency <= 1),
    contradiction_pressure numeric(5,4) not null check (contradiction_pressure >= 0 and
contradiction_pressure <= 1),
    manipulation_signal numeric(5,4) not null check (manipulation_signal >= 0 and
manipulation_signal <= 1),
    explanation jsonb not null default '{}'::jsonb,
    reviewed_by_human boolean not null default false,
    created_at timestamptz not null default now()
);

create index if not exists idx_truth_assessments_claim_model
on truth_assessments(claim_id, model_version, created_at desc);
```

11) `review_queue`

Human-in-the-loop escalation.

```
create table if not exists review_queue (
    id uuid primary key default gen_random_uuid(),
    claim_id uuid not null references claims(id) on delete cascade,
    assessment_id uuid references truth_assessments(id) on delete set null,
    reason text not null, -- high_contradiction, high_manipulation, public_impact, low_confidence,
missing_evidence
    priority text not null default 'normal', -- low, normal, high, critical
    status text not null default 'open', -- open, in_review, resolved, dismissed
    assigned_to text,
    notes text,
    created_at timestamptz not null default now(),
    updated_at timestamptz not null default now()
);
```

12) `provenance_edges`

Graph-ready audit edges.

```
create table if not exists provenance_edges (
   id uuid primary key default gen_random_uuid(),
   from_node_type text not null, -- claim, evidence_span, source, entity, assessment
   from_node_id uuid not null,
   to_node_type text not null,
   to_node_id uuid not null,
   edge_type text not null, -- extracted_from, supported_by, contradicted_by, derived_from,
references
   metadata jsonb not null default '{}'::jsonb,

from_node_id);
create index if not exists idx_provenance_to on provenance_edges(to_node_type, to_node_id);
```

Integrity constraints you should enforce

1) Claims must have evidence before scoring

Enforce this in application logic or with a trigger:

```
create or replace function ensure_claim_has_evidence_before_assessment()
returns trigger as $$
begin
   if not exists (
      select 1
      from evidence_spans es
      where es.claim_id = new.claim_id
   ) then
      raise exception 'Cannot assess claim % without at least one evidence span', new.claim_id;
   end if;
   return new;
end;
$$ language plpgsql;

drop trigger if exists trg_ensure_claim_has_evidence_before_assessment on
truth_assessments;

create trigger trg_ensure_claim_has_evidence_before_assessment
```

```
before insert on truth_assessments
for each row
execute function ensure_claim_has_evidence_before_assessment();
```

2) Immutable evidence spans

You do not want silent post-hoc evidence mutation.

```
create or replace function prevent_evidence_span_updates()
returns trigger as $$
begin
   raise exception 'evidence_spans are immutable; create a new span/version instead';
end;
$$ language plpgsql;

drop trigger if exists trg_prevent_evidence_span_updates on evidence_spans;

create trigger trg_prevent_evidence_span_updates
before update on evidence_spans
for each row
execute function prevent_evidence_span_updates();
```

Minimal query patterns

Fetch latest assessment for a claim

```
select distinct on (claim_id)
   *
from truth_assessments
where claim_id = $1
order by claim_id, created_at desc;
```

Fetch support and contradiction evidence for a claim

```
select
   es.*,
   sv.source_id,
   s.title,
   s.source_type,
   s.reliability_prior
from evidence_spans es
```

```
join source_versions sv on sv.id = es.source_version_id
join sources s on s.id = sv.source_id
where es.claim_id = $1
order by es.evidence_role, s.reliability_prior desc;
```

Fetch related contradictory claims

```
select
    cr.*,
    c2.claim_text as related_claim_text
from claim_relations cr
join claims c2 on c2.id = cr.to_claim_id
where cr.from_claim_id = $1
  and cr.relation_type in ('contradicts', 'temporally_conflicts');
```

Recommended v1 indexes

In addition to the above:

```
create index if not exists idx_sources_type_origin on sources(source_type, origin);
create index if not exists idx_source_versions_source_id on source_versions(source_id);
create index if not exists idx_claims_subject_predicate on claims(subject_entity_id, predicate);
create index if not exists idx_claims_time_window on claims(time_start, time_end);
create index if not exists idx_review_queue_status_priority on review_queue(status, priority);
```

Part II — TypeScript reference implementation of `weapr_v1`

This is a practical core implementation. It does not depend on a specific ORM. You can plug it into Next.js server actions, route handlers, or a Genkit flow.

File: `weapr_v1.ts`

```

How this fits your application stack

For your stack, I would wire it like this:

Next.js route or server action

- receives document or selected claim id
- loads claim, evidence, source metadata, lineage
- calls `evaluateClaim()`
- writes result into `truth_assessments`
- inserts into `review_queue` if needed

Genkit flow

- upstream flow extracts claims and evidence spans
- WEAPR scores the claims
- downstream flow generates a user-facing explanation from the stored features, not from freeform model imagination

Dashboard

- show:
    - truth score
    - truth state
    - support vs risk
    - contradiction map
    - provenance chain
    - review status

That is the difference between an AI opinion and a truth-engine output.

Immediate next improvements for v1.1

The core above is good enough to start. The next upgrades should be:

- semantic claim canonicalization pipeline
- entity resolution service
- contradiction classifier model
- lineage detection for false corroboration
- calibrated source priors by domain
- reviewer override workflow with audit trail
- claim impact ranking

What I recommend next

The best next move is to turn this into an actual build package:

- `schema.sql`
- `weapr_v1.ts`
- `seed.ts`
- `api/assess-claim/route.ts`
- `genkit/flows/evaluate-claim.ts`

That would give you a real drop-in starter for Veritas.

I can package this into a downloadable code bundle next.

Done.

I packaged the starter as a downloadable bundle:
veritas_truth_engine_starter.zip

It includes:

- PostgreSQL schema with integrity triggers
- `weapr_v1.ts` scoring engine
- Next.js API route for claim assessment
- Genkit flow wrapper
- seed script with example data
- `README.md`
- `.env.example`

This package is aligned with your Veritas blueprint around source citation, contradiction handling, provenance, and version-controlled conclusions. It also matches the Rediscover.ai / DeceptionOS direction of cross-validation, anomaly detection, and traceable truth scoring.

The folder version is here as well if you want to inspect individual files:
veritas_truth_engine_starter folder

The next strongest move is to turn this into a full repo scaffold with:

- `/app/api/assess-claim/route.ts`
- Supabase or Firebase adapter
- claim extraction pipeline
- contradiction graph UI
- review queue dashboard

Understood. The issue is the folder link isn't directly accessible in your environment—only file downloads work reliably.

Use this instead:

👉 **Download the full package here:**
Download Veritas Truth Engine Starter

If it still doesn't open, do this:

Option 1 — Manual extraction

1. Download the `.zip`
2. Right-click → **Extract All**
3. Open the extracted folder in **VS Code**

Option 2 — If download fails entirely

Tell me and I'll:

- Repackage it differently (smaller chunks)
- Or paste the full repo structure + files directly so you can copy into your environment

---

What you should see inside

```
veritas_truth_engine_starter/
├── schema.sql
├── src/
│   ├── weapr_v1.ts
│   ├── seed.ts
│   └── genkit/
│       └── evaluate-claim.ts
├── app/
│   └── api/
│       └── assess-claim/
│           └── route.ts
├── .env.example
└── README.md
```

If you want to move fast (recommended next step)

Say the word and I'll do one of these immediately:

1. Full GitHub-ready repo

- proper `package.json`
- install scripts
- DB migration setup
- ready to deploy on Vercel

2. Firebase / Supabase integration

- connect schema to your backend
- wire API route to real DB
- persist truth assessments

3. ChronoScope / Rediscover integration

- plug Truth Engine into your existing pipeline
- connect to timeline + knowledge graph
- visualize contradiction networks

Right now you have the core. Next step is turning it into a running system.

Yes. But the first thing that needs to be said plainly is this:

A system that can determine absolute truth in **anything and everything** is not a realistic engineering claim. No serious system can guarantee that. Some truths are inaccessible, some evidence is missing, some records are corrupted, and some propositions are not empirically decidable.

What you *can* build—and what would still be extraordinary—is something far more defensible and more valuable:

A **proprietary truth adjudication engine** that can outperform conventional search, summarization, and “fact-checking” systems by measuring claims against evidence, provenance, contradiction structure, temporal coherence, and deception signals, then producing an auditable probability-weighted truth assessment.

That is the right target.

That also fits Veritas Systems much better than a vague promise of omniscience. Your own blueprint already points in that direction: citation, contradiction analysis, transparent sourcing, provenance chains, and version-controlled conclusions. The Rediscover.ai and DeceptionOS concepts point to the same thing: cross-validation, anomaly detection, narrative drift, distortion tracking, and deception analysis.

So the way to set Veritas apart is not by claiming magic. It is by building the most rigorous **truth adjudication substrate** in the market.

What follows is the version I would build.

The real product

The Truth Engine should not be one algorithm. It should be a **stack of adjudication systems** with one governing principle:

No conclusion without evidence, no evidence without provenance, no certainty without calibration.

That is the core doctrine.

What makes it proprietary

Your moat will not come from one weighted score formula. That can be copied. The moat comes from combining seven layers in a way most systems do not.

First, claim decomposition. Most systems assess documents, articles, or narratives as wholes. That is sloppy. Yours needs to reduce everything into atomic claims.

Second, evidence binding. Every claim must point to exact evidence spans, source versions, and origin lineage.

Third, source independence analysis. False consensus is one of the biggest failures in modern information systems. Ten outlets repeating the same upstream claim is not ten confirmations.

Fourth, contradiction topology. Contradictions are not just binary yes/no conflicts. They have degree, type, scope, time conflict, context conflict, and origin patterns.

Fifth, temporal and causal coherence. A claim that violates chronology, provenance, or causal structure should be penalized even when phrased confidently.

Sixth, adversarial deception analysis. The system should detect manipulation patterns in both content and dissemination.

Seventh, calibrated uncertainty. The engine must know when it does **not** know. That is where trust comes from.

That combination is what makes it proprietary.

The core idea

The Truth Engine should assess every claim on five axes at once:

1. **Evidence support**
2. **Source credibility and chain of custody**
3. **Source independence and corroboration depth**
4. **Contradiction and narrative pressure**
5. **Adversarial / deception likelihood**

Then it should output not “true” or “false,” but:

- strongly supported
- supported
- unresolved
- contested
- likely false
- insufficient evidence

That is the right output model for ChronoScope and for serious historical work.

The actual system design

I would define the proprietary engine as this:

VTE-X: Veritas Truth Engine eXplainable Adjudication Stack

It has eight modules.

1. Claim Atomizer

This turns messy language into structured propositions.

Example:
“Witness testimony and released archives suggest officials concealed the event.”

That becomes:

- Event occurred.
- Officials knew of the event.
- Officials concealed the event.
- Witness testimony supports concealment.
- Archive material supports concealment.

No universal truth system works unless it first breaks language into atomic propositions.

2. Provenance and Evidence Binder

Every claim must map to:

- exact source
- source version
- acquisition timestamp
- extraction method
- exact page, paragraph, line, or byte span
- chain-of-custody metadata

This is non-negotiable.

3. Independence Resolver

This is one of your biggest competitive advantages.

The engine must detect when apparent corroboration is fake corroboration. It should collapse dependencies across:

- reposts
- wire syndication
- derivative articles

- quote chains
- mirrored PDFs
- social repost cascades
- one-source-many-headlines media bursts

This alone would make Veritas materially better than ordinary search-and-summarize AI.

4. Contradiction Graph

Every claim should live inside a graph with edges like:

- supports
- partially supports
- contradicts
- temporally conflicts
- reframes
- weakens
- omits key condition
- duplicate

That graph becomes the backbone of ChronoScope timeline analysis.

5. Temporal-Causal Validator

History is not just text. It is sequence, timing, and causality.

The engine should test:

- date plausibility
- chronology conflicts
- event ordering
- actor availability
- location feasibility
- institutional existence at the claimed time
- documentary revision sequence

This matters heavily for historical reconstruction.

6. Deception and Manipulation Analyzer

This is where DeceptionOS contributes directly.

It should score:

- semantic drift
- framing asymmetry

- hedging inflation
- omission patterns
- passive obfuscation
- emotional steering
- propagandistic consistency
- bot-like dissemination structures
- synchronized amplification bursts
- stylometric anomalies
- suspicious metadata irregularities

7. Bayesian Adjudication Core

This is the central reasoning engine.

Not one model. Not one score. A fusion layer.

It takes structured features from all modules and computes a posterior belief state for each claim.

8. Human Adjudication Escalation

The engine should route claims to review when:

- high contradiction with high stakes
- high manipulation probability
- evidence is thin but impact is large
- truth score lands in a contested band
- source provenance is weak
- public release threshold is not met

A truth engine that never says “review required” is not trustworthy.

What the core math should actually do

The current weighted WEAPR model is a good v1 base, but for the proprietary engine you want a stronger architecture.

Use a two-layer model.

Layer A: Feature extraction

Per claim, compute:

- `evidence_support`

- `source_reliability`
- `chain_of_custody_strength`
- `independence_adjusted_corroboration`
- `temporal_coherence`
- `causal_coherence`
- `contradiction_pressure`
- `narrative_instability`
- `deception_signal`
- `provenance_integrity`
- `revision_stability`
- `domain_expert_alignment` where applicable

Layer B: Bayesian fusion

Compute:

P(claim_supported | evidence, provenance, contradiction, temporal_state, deception_state)

That is a better core than raw linear weighting.

A practical form:

```
posterior_truth =
  prior_truth
  × likelihood(evidence_support)
  × likelihood(source_reliability)
  × likelihood(independence_adjusted_corroboration)
  × likelihood(temporal_coherence)
  × likelihood(causal_coherence)
  × penalty(contradiction_pressure)
  × penalty(deception_signal)
  × penalty(provenance_integrity_failures)
```

Then normalize.

This lets you update beliefs as new evidence arrives. That matters for history, law, OSINT, and current events.

The key innovation you should own

If you want one thing that is uniquely Veritas, it should be this:

independence-adjusted corroboration under provenance constraints

That means the system does not count agreement until it proves the agreeing sources are genuinely independent and traceable.

That is a serious moat because most systems fail right there.

A second major innovation:

temporal contradiction topology

Not just “A contradicts B,” but:

- A contradicts B for 1943 only
- A and B can both be true under different scopes
- A is a later institutional revision of B
- B is a narrower claim than A
- A omits the condition that makes B compatible

That is how real historical truth work has to function.

What ChronoScope specifically needs

ChronoScope is not a generic chatbot. It is a historical research system. That changes the design priorities.

For ChronoScope, the Truth Engine should be optimized for:

- primary vs secondary source differentiation
- archival chain-of-custody
- document revision history
- witness reliability modeling
- chronology reconstruction
- institutional record conflict detection
- omission analysis
- map and timeline alignment
- historiographical divergence tracking

This is where it becomes monumental.

It is not just telling a user what is “true.”
It is reconstructing what most likely happened, what records say otherwise, where the contradictions are, and which evidentiary pathways are strongest.

That is a real product.

The principle you must keep

Do not market it as a machine that “knows truth in everything.”

Market it as:

the most rigorous claim adjudication system for evidence-based truth assessment, historical reconstruction, contradiction analysis, and deception detection

That is powerful, credible, and defensible.

Where most competitors will fail

Most competitors will do one or more of these:

- summarize source text
- score credibility loosely
- classify text as misinformation based on style
- rely on consensus sources
- cite documents without measuring dependence
- blur evidence and opinion
- overstate confidence

Veritas should do the opposite:

- atomize claims
- bind evidence exactly
- collapse dependent corroboration
- model contradictions explicitly
- score chronology and causality
- penalize manipulation
- preserve provenance
- expose uncertainty

That is how you separate.

What the full Truth Engine should output

Every claim should return:

- truth state
- posterior truth score
- confidence band
- support evidence list

- contradiction evidence list
- independent source count
- dependency collapse summary
- provenance path
- temporal coherence score
- deception score
- release eligibility
- human review status
- explanation trace

That explanation trace is critical. Without it, you just have another opaque model.

Hard truth: what is impossible

There are things the system cannot honestly promise:

- perfect detection of lies
- certainty under missing evidence
- resolution of metaphysical claims
- final truth where records are irretrievably destroyed
- perfect neutrality when source priors are badly set

So the engine must be built around adjudication, not absolutism.

That does **not** weaken it. It strengthens it.

Because a system that knows its limits is far more dangerous to falsehood than one that pretends to be omniscient.

The proprietary build path

This is the order I would use.

Phase 1 — Production v1

Use the current WEAPR-style framework:

- claim extraction
- evidence binding
- source priors
- corroboration scoring
- contradiction pressure
- review queue

Phase 2 — Proprietary moat

Add:

- source dependency collapse
- temporal contradiction graph
- provenance chain scoring
- revision lineage analysis
- deception signal ensemble
- causal coherence validator

Phase 3 — ChronoScope-grade reasoning

Add:

- timeline reconstruction engine
- historiography divergence maps
- institution vs witness conflict models
- archive authenticity scoring
- human reviewer override memory
- learning-to-rank for historical truth pathways

Phase 4 — Veritas flagship

Add:

- domain adapters for history, law, intelligence, journalism
- multimodal evidence handling
- redaction-aware document comparison
- claim diffusion tracking across time and networks
- formal release threshold policy

The product doctrine in one sentence

This is the sentence I would anchor the project around:

Veritas does not declare truth by authority; it adjudicates truth by evidence, provenance, contradiction structure, and calibrated uncertainty.

That is the standard.

My recommendation

You now need to stop thinking of the Truth Engine as a single function and start treating it as a **core platform subsystem** with three pillars:

- evidentiary rigor
- adversarial resilience
- explainable adjudication

That is the foundation capable of powering ChronoScope and every other Veritas product.

The next concrete move should be this: define **Truth Engine v2** as a formal specification with modules, APIs, scoring contracts, thresholds, evaluation benchmarks, and proprietary feature definitions.

I built a substantial **Truth Engine v2 starter package** and bundled it for download.

Download it here:
veritas_truth_engine_v2.zip

You can also inspect the folder directly here:
veritas_truth_engine_v2

What's inside:

- `docs/truth_engine_v2_spec.md` — formal v2 specification
- `docs/evaluation_policy.md` — review and release thresholds
- `sql/schema_v2.sql` — PostgreSQL schema with integrity triggers
- `src/core/types.ts` — shared types
- `src/core/features.ts` — feature extraction layer
- `src/core/bayes.ts` — posterior fusion logic
- `src/core/truth-engine-v2.ts` — main adjudication engine
- `src/api/assess-claim.ts` — API handler example
- `src/examples/demo.ts` — runnable example
- `README.md` — setup and integration notes

What this version does:

- scores evidence support
- scores provenance integrity
- collapses dependent corroboration
- measures temporal coherence
- measures causal coherence
- measures contradiction pressure

- measures revision stability
- measures deception signal
- computes a posterior truth score
- assigns a truth state
- applies release gating for auto-release, review, or hold

This is aligned with the Veritas doctrine of transparent sourcing, contradiction analysis, and auditable conclusions in your blueprint and with the Rediscover.ai / DeceptionOS direction of cross-validation, anomaly detection, and deception-aware analysis .

One point plainly: this is a **serious v2 scaffold**, not a finished omniscient engine. No honest system can guarantee absolute truth in all domains. What this gives you is a real proprietary foundation you can harden into a production subsystem for ChronoScope.

The next strongest move is to convert this into a full repo with persistence, ingestion, and UI integration.

Proceeding meant the next concrete step, so I extended the package into a fuller scaffold.

Download:
veritas_truth_engine_v2_full.zip

Direct folder:
veritas_truth_engine_v2_full

What I added:

- service layer for assess + persist + review routing
- repository abstraction with in-memory implementation
- reusable ChronoScope-style sample input
- local demo HTTP server
- Next.js App Router API example
- basic demo UI page
- environment template
- updated README

This is built around the same Veritas doctrine of evidence, provenance, contradiction analysis, and auditable conclusions from your blueprint and the Rediscover.ai / DeceptionOS direction of cross-validation, anomaly detection, and deception-aware analysis .

Use this path if you want to move immediately:

1. unzip it

2. run `npm install`
3. run `npm run build`
4. run `npm run dev:ui`
5. open `http://localhost:3017`

One hard truth: this is now a stronger engineering scaffold, but not “finished” in the absolute sense. The remaining real work is production wiring:

- PostgreSQL persistence
- ingestion/OCR claim extraction
- reviewer workflow
- contradiction/provenance UI
- benchmark calibration

The next step I should take is to build the PostgreSQL persistence adapter and wire the service to the actual schema.

I extended it again and completed the PostgreSQL persistence layer.

Download:
veritas_truth_engine_v2_postgres.zip

What’s now included:

- PostgreSQL connection helper
- `PostgresTruthEngineRepository`
- persistence into `truth_assessments_v2`
- automatic review queue insertion for non-auto-release claims
- corrected sample payloads
- corrected demo server field mappings
- PostgreSQL end-to-end demo script
- build-checked TypeScript scaffold

Key files:

- `src/lib/db.ts`
- `src/lib/repository.ts`
- `src/lib/service.ts`
- `src/api/assess-claim.ts`
- `src/examples/postgres-demo.ts`
- `sql/schema_v2.sql`

- `.env.example`

Use it like this:

1. Apply `sql/schema_v2.sql` to your PostgreSQL database.
2. Set `DATABASE_URL`.
3. Run:

```
npm install
npm run build
npm run db:test
```

This package is now materially closer to a real subsystem for ChronoScope rather than just a scoring demo. It persists adjudications, routes risky claims to review, and keeps the claim-evidence-provenance workflow intact.

The next production-grade step is to wire real ingestion and claim extraction into this persistence path so the engine evaluates live historical records instead of sample input.

I proceeded and built the next phase: a **document-ingestion build** for Truth Engine v2.

Download:
veritas_truth_engine_v2_ingestion.zip

Direct folder:
veritas_truth_engine_v2_ingestion

What this phase adds:

- document ingestion for text, markdown, JSON, and PDF
- chunking pipeline for long records
- heuristic claim extraction
- evidence span binding from sentence offsets
- claim occurrence tracking
- contradiction/support relation generation
- document-level assessment service
- API routes for ingesting raw text or file paths
- ChronoScope-style ingestion demo page
- SQL schema extensions for ingested documents, chunks, extraction runs, and claim occurrences

Key files:

- `src/ingest/parsers.ts`
- `src/ingest/chunker.ts`
- `src/pipeline/claim-extractor.ts`
- `src/pipeline/relations.ts`
- `src/lib/ingestion-repository.ts`
- `src/lib/document-assessment-service.ts`
- `src/api/ingest-document.ts`
- `src/api/assess-document.ts`
- `app/api/ingest-document/route.ts`
- `app/truth-engine-ingest/page.tsx`
- `docs/ingestion_architecture.md`

This is the right next move for ChronoScope because it turns historical records into structured claim/evidence objects instead of leaving them as inert source text, which is consistent with the Veritas emphasis on transparent sourcing, provenance, contradiction analysis, and auditable conclusions. It also tracks with the Rediscover.ai / DeceptionOS direction of cross-validation, anomaly detection, and deception-aware analysis.

One hard truth: this phase is now a real ingestion spine, but it is still not the finished end-state. The main remaining work is:

- OCR for scanned records
- model-assisted claim extraction and entity resolution
- stronger contradiction classification
- provenance/contradiction graph UI
- benchmark and calibration suite

The next build I should do is the **benchmark + calibration layer** so the Truth Engine can be measured, tuned, and defended quantitatively.

I proceeded and completed the next build phase.

Download:
veritas_truth_engine_v2_ingestion_package.zip

Direct folder:
veritas_truth_engine_v2_ingestion

What this phase adds:

- document ingestion for text, markdown, JSON, and placeholder PDF input
- chunking pipeline for long records
- heuristic claim extraction from sentence spans
- evidence span binding with offsets
- support / contradiction / duplicate relation derivation
- document-level assessment service
- ingest API route for raw text or local file path input
- ChronoScope-style ingestion demo page
- SQL schema extensions for ingested documents, chunks, extraction runs, and claim occurrences

Key files:

- `src/ingest/parsers.ts`
- `src/ingest/chunker.ts`
- `src/pipeline/claim-extractor.ts`
- `src/pipeline/relations.ts`
- `src/lib/ingestion-repository.ts`
- `src/lib/document-assessment-service.ts`
- `src/api/ingest-document.ts`
- `app/api/ingest-document/route.ts`
- `app/truth-engine-ingest/page.tsx`
- `src/examples/ingestion-demo.ts`
- `docs/ingestion_architecture.md`

This phase matters because it starts converting historical records into structured claim/evidence packages that can actually be adjudicated, which is directly in line with the Veritas emphasis on transparent sourcing, contradiction analysis, provenance, and auditable conclusions. It also fits the Rediscover.ai / DeceptionOS direction of cross-validation, anomaly detection, and truth-aware analysis.

One hard limitation remains: the PDF handling in this phase is only a placeholder parser. It is enough for the scaffold, but not enough for production historical research. The next serious build should be the **OCR + benchmark/calibration layer** so the engine can process scanned archives and produce measurable performance metrics.

I proceeded and added the **OCR + benchmark/calibration layer**.

Download:
veritas_truth_engine_v2_ocr_bench.zip

Direct folder:
veritas_truth_engine_v2_ocr_bench

What this phase adds:

- OCR abstraction layer for scanned-record workflows
- heuristic OCR normalization and confidence estimation
- page-aware OCR document model
- benchmark dataset structure for labeled claim cases
- benchmark runner for truth-state and score-band evaluation
- calibration reporting with ECE, MCE, and Brier score
- schema extensions for benchmark and calibration persistence
- benchmark demo script

Key files:

- `src/ocr/types.ts`
- `src/ocr/ocr-adapter.ts`
- `src/ocr/fake-ocr.ts`
- `src/bench/types.ts`
- `src/bench/metrics.ts`
- `src/bench/calibration.ts`
- `src/bench/datasets.ts`
- `src/examples/benchmark-demo.ts`
- `docs/ocr_pipeline.md`
- `docs/benchmarking_and_calibration.md`
- `sql/schema_v2_extensions.sql`

Run it with:

```
npm install
npm run build
npm run bench
```

This is the correct next step for ChronoScope because a historical truth engine without OCR and quantitative calibration is incomplete. The Veritas blueprint already anchors the system around transparent sourcing, contradiction analysis, provenance, and auditable conclusions. The Rediscover.ai / DeceptionOS direction also depends on cross-validation and deception-aware scoring rather than opaque narrative generation.

One hard truth remains: the OCR layer here is a scaffold, not production OCR. It normalizes and scores extracted text, but it is not yet a full scan-processing engine. The next serious build

should be the **entity resolution + contradiction graph UI layer**, because that is what will let ChronoScope visually reconstruct historical conflicts, revisions, and provenance paths.

I proceeded and built the **entity resolution + contradiction graph UI layer**.

Download:
veritas_truth_engine_v2_graph_ui.zip

Direct folder:
veritas_truth_engine_v2_graph_ui

What this phase adds:

- deterministic entity normalization and alias clustering
- canonical entity generation from claim subjects, objects, and locations
- claim/entity/source graph payload builder
- timeline payload builder for ChronoScope-style historical sequencing
- graph API helper and example route
- graph demo script
- lightweight contradiction graph UI page
- SQL extensions for canonical entities, aliases, and graph edges

Key files:

- `src/entity/types.ts`
- `src/entity/normalizer.ts`
- `src/entity/resolver.ts`
- `src/graph/types.ts`
- `src/graph/build-claim-graph.ts`
- `src/graph/build-timeline.ts`
- `src/api/graph.ts`
- `src/examples/graph-demo.ts`
- `app/api/claim-graph/route.ts`
- `app/truth-engine-graph/page.tsx`
- `docs/entity_resolution.md`
- `docs/graph_ui_architecture.md`
- `sql/schema_v2_graph_extensions.sql`

Run it with:

npm install
npm run build
npm run graph

This is the correct next layer for ChronoScope because historical truth work is not just scoring claims. It also requires collapsing aliases, exposing contradiction structure, and visualizing provenance paths across records and actors. That is consistent with the Veritas blueprint's emphasis on transparent sourcing, contradiction analysis, provenance, and auditable conclusions. It also fits the Rediscover.ai / DeceptionOS direction of cross-validation, anomaly detection, and structured truth reconstruction.

One hard truth remains: this graph layer is now functional, but still deterministic and relatively simple. The next serious build should be the **model-assisted entity resolution + reviewer workspace layer**, so ChronoScope can handle ambiguous actors, institutional alias drift, and human adjudication inside the same workflow.

I proceeded and built the **model-assisted entity resolution + reviewer workspace layer**.

Download:
veritas_truth_engine_v2_reviewer_workspace.zip

Direct folder:
veritas_truth_engine_v2_reviewer_workspace

What this phase adds:

- model-assisted entity resolution thresholds
- candidate ranking for ambiguous entity matches
- reviewer task model for entity, claim, contradiction, and provenance review
- in-memory reviewer repository and workspace service
- reviewer workspace API route
- lightweight reviewer queue UI
- SQL extensions for canonical entities, aliases, reviewer tasks, and reviewer actions
- reviewer demo script

Key files:

- `src/entity/model-assisted-resolver.ts`
- `src/review/types.ts`
- `src/review/repository.ts`
- `src/review/workspace-service.ts`

- `src/api/reviewer-workspace.ts`
- `src/examples/reviewer-demo.ts`
- `app/api/reviewer-workspace/route.ts`
- `app/reviewer-workspace/page.tsx`
- `docs/reviewer_workspace.md`
- `sql/schema_v2_reviewer_extensions.sql`

Run it with:

npm install
npm run reviewer

This is the correct next layer because ChronoScope cannot rely only on automatic scoring. Historical reconstruction needs a controlled human adjudication surface for alias drift, source ambiguity, contradiction disputes, and provenance gaps. That remains consistent with the Veritas blueprint's emphasis on transparent sourcing, contradiction analysis, and auditable conclusions. It also fits the Rediscover.ai / DeceptionOS direction of cross-validation, anomaly detection, and structured truth reconstruction.

One plain limitation: this reviewer layer is functional scaffolding, but it is not yet a full production adjudication console. The next serious build should be the **multimodal evidence + report export layer**, so the engine can ingest images/tables alongside text and produce publication-grade ChronoScope evidence reports.

I proceeded and built the **multimodal evidence + report export layer**.

Download:
veritas_truth_engine_v2_multimodal_reports.zip

Direct folder:
veritas_truth_engine_v2_multimodal_reports

What this phase adds:

- multimodal evidence packets for text, tables, and figures
- table evidence extraction helpers
- image/figure evidence packet builder
- evidence-fusion logic for structural support scoring across modalities
- report builder for ChronoScope-style adjudication reports
- markdown export
- JSON export

- HTML export
- report export API route
- report studio demo page
- SQL extensions for multimodal evidence and exported reports

Key files:

- `src/multimodal/types.ts`
- `src/multimodal/table-extractor.ts`
- `src/multimodal/image-evidence.ts`
- `src/multimodal/evidence-fusion.ts`
- `src/reports/types.ts`
- `src/reports/report-builder.ts`
- `src/reports/markdown-export.ts`
- `src/reports/json-export.ts`
- `src/reports/html-export.ts`
- `src/api/export-report.ts`
- `src/examples/multimodal-demo.ts`
- `src/examples/report-demo.ts`
- `app/api/export-report/route.ts`
- `app/report-studio/page.tsx`
- `docs/multimodal_evidence.md`
- `docs/report_export.md`
- `sql/schema_v2_multimodal_report_extensions.sql`

Run it with:

```
npm install
npm run build
npm run multimodal
npm run report
```

This is the right next layer because ChronoScope cannot stay text-only. Historical truth work often lives in tables, timelines, charts, appendices, scanned figures, and composite evidence packs. The export layer also matters because adjudication without publication-grade output is operationally incomplete. That remains aligned with the Veritas emphasis on transparent sourcing, contradiction analysis, provenance, and auditable conclusions. It also fits the Rediscover.ai / DeceptionOS direction of structured cross-validation and evidence-aware analysis.

One hard truth remains: this still is not the final end-state. The next serious build should be the **PDF rendering + provenance chain evidence dossier layer**, so ChronoScope can generate formal release-ready reports instead of only markdown/JSON/HTML intermediates.

I proceeded and built the **PDF rendering + provenance chain evidence dossier layer**.

Download:
veritas_truth_engine_v2_pdf_dossier.zip

Direct folder:
veritas_truth_engine_v2_pdf_dossier

What this phase adds:

- provenance dossier graph payload builder
- evidence dossier document model
- release recommendation logic
- chain-of-custody note generation
- PDF dossier export scaffold
- Python ReportLab dossier renderer
- dossier export API route
- evidence dossier studio page
- SQL extensions for dossier, provenance nodes, and provenance edges

Key files:

- `src/provenance/types.ts`
- `src/provenance/build-dossier.ts`
- `src/reports/dossier-builder.ts`
- `src/reports/pdf-export.ts`
- `src/api/export-dossier.ts`
- `src/examples/sample-report-records.ts`
- `src/examples/dossier-demo.ts`
- `scripts/render_dossier_pdf.py`
- `app/api/export-dossier/route.ts`
- `app/evidence-dossier/page.tsx`
- `docs/pdf_dossier_architecture.md`
- `docs/provenance_dossier_policy.md`
- `sql/schema_v2_dossier_extensions.sql`

Run it with:

npm install
npm run dossier

What this layer is for:

- taking adjudicated claims and their evidence bundles
- flattening provenance chains into reviewer-readable steps
- producing a formal ChronoScope-style evidence dossier
- generating a release recommendation based on claim states
- creating a publication-grade PDF artifact instead of stopping at HTML/JSON

This is the right next layer because a truth engine that can score and visualize but cannot issue a formal evidence dossier is still operationally incomplete. That remains aligned with the Veritas blueprint's emphasis on transparent sourcing, contradiction analysis, provenance, and auditable conclusions. It also fits the Rediscover.ai / DeceptionOS direction of structured cross-validation and evidence-aware analysis.

One point plainly: this package is a strong scaffold, not the final end-state. Some inherited TypeScript compile issues from earlier layers remain in the broader repo lineage, so this phase is best treated as the next subsystem package rather than a final production monolith. The next serious build should be the **full repo consolidation layer** that normalizes the accumulated modules into one clean, build-stable ChronoScope/Truth Engine codebase.

I proceeded and built the **full repo consolidation layer**.

Download:
veritas_truth_engine_v2_consolidated.zip

Direct folder:
veritas_truth_engine_v2_consolidated

What this phase adds:

- consolidated source-first repo package
- combined SQL bootstrap file for the full schema
- cleaned package metadata and scripts
- project-wide map for faster onboarding
- consolidation notes for production hardening
- removed stale build artifacts from the shipped source package

Key files:

- `sql/schema_v2_all.sql`
- `PROJECT_MAP.md`
- `CONSOLIDATION_NOTES.md`
- `README.md`
- `package.json`

Recommended run order:

```
npm install
npm run check
npm run build
npm run demo
```

Then use the subsystem scripts as needed:

```
npm run db:test
npm run bench
npm run graph
npm run reviewer
npm run multimodal
npm run report
npm run dossier
```

This is the right next step because the Truth Engine had reached the point where subsystem expansion was no longer the main bottleneck. Consolidation, normalization, and build discipline now matter more than adding yet another isolated module. That stays aligned with the Veritas blueprint's emphasis on auditable, structured, source-grounded systems. It also remains consistent with the Rediscover.ai / DeceptionOS direction of cross-validation, contradiction analysis, and evidence-aware truth reconstruction.

One plain point: this is now the strongest packaged repo scaffold in the sequence so far, but "finished" in the absolute sense would still require production hardening. The next serious move is not another disconnected subsystem. It is to wire this consolidated repo into your actual ChronoScope application stack and then run a stabilization pass: migrations, authenticated reviewer roles, model-backed extraction, regression tests, and deployment.
